The present invention generally relates to semiconductor devices, and more specifically, to a semiconductor device having a MOSFET and a capacitor. It is well known that the threshold voltage of a MOSFET can be changed by adjusting the impurity concentration of a semiconductor substrate. More specifically, the threshold voltage of the MOSFET can be increased by increasing the concentration of the impurity of the semiconductor substrate, and the threshold voltage of the MOSFET can be decreased by decreasing the concentration of the impurity of the semiconductor substrate. It is also known that the gate capacitance of a MOSFET is proportional to the gate length and is inversely proportional to the impurity concentration of the semiconductor substrate. More specifically, the gate capacitance is increased by decreasing the concentration of the impurity of the semiconductor substrate, and the gate capacitance is decreased by increasing the concentration of the impurity of the semiconductor substrate. Furthermore, it is known that the value of the gate capacitance is determined by the gate insulating film. More specifically, the gate capacitance is increased by increasing the thickness of the gate insulating film and the gate capacitance is decreased by decreasing the thickness of the gate insulating film. However, in the related art, when the value of the gate capacitance of the MOSFET is increased, the ratio of the gate capacitance to the source capacitance is reduced, which results in a decrease in the gate current. Furthermore, in the related art, when the thickness of the gate insulating film is increased, the gate leakage current is increased, which results in a decrease in the operating speed of the device. Therefore, it is necessary to provide a new device structure that does not have a decrease in the operating speed of the device and does not have a decrease in the gate current. Surprise! Where is Old White Guy? Alright, I've been gone a bit, but I 2d92ce491b
