Field of the Invention The present invention relates to a method and apparatus for processing a color image having three primary colors. 2. Description of the Prior Art A color image display tube used in a television receiver is basically composed of a fluorescent surface, a shadow-mask and a screen. The fluorescent surface is constructed in such a manner that three primary colors, i.e. red, green and blue colors are formed on one of the inner and outer walls of the fluorescent surface. The shadow-mask is mounted in such a manner that phosphors, which are excited by light beams having passed through the screen, are combined with the three primary colors. In the field of color image display tubes, there is an increasing demand for a color image display tube having a large display screen. In the case of a color image display tube of a large size, the magnification of a projection screen is of importance. Further, in the case of a color image display tube for a projection television receiver, the color separation of a color image display tube should be minimized in order to prevent color separation by interference between adjacent color images. In the case of a color image display tube wherein a shadow-mask is used, color separation can be reduced by suppressing light beams of the three primary colors projected onto the shadow-mask. By a method of reducing color separation in this manner, it is possible to realize a high-quality display. In a color image display tube wherein a shadow-mask is used, when the color separation between the three primary colors is reduced, it is necessary to increase the number of beam passageways of a shadow-mask in order to support a large display screen. In other words, in the case of a color image display tube of a large screen, there are problems in that the method for decreasing the size of an aperture to be formed in the shadow-mask is restricted and that light beams of the three primary colors are excessively spread and cannot be projected sufficiently.
