Encrypt: Base64 encode (AES-128) and hexencode (Keccak-256) any piece of text for safe storage in an encrypted version. Decrypt: Decode the encrypted base64 string to its hexencode equivalent and decrypt the hexencode string to get the original text. Edit Mode: Although the base64 version can be copied to the clipboard, the hexencode version is much more secure, and deleting it is just a matter of closing the hex editor, and doesn't involve having to delete the corresponding file. Convert Mode: Change selected text in the hex editor to the equivalent base64 version. Show Password: Shows the password in clear (but if you have one set up, it can be used to decrypt the output). Encrypt/Decrypt Clients: Supports AES-128 and Keccak-256 encryption algorithms. Both can be used in an easy to select button or a dialog to enable or disable. How is it better than Keeppass or other password managers? Well, the biggest problem is that you have to keep a huge amount of data stored in your "external memory" to do anything useful with Wuul Crypto Text Cracked Version. Compared to Keeppass, for example, a single 24x24 pixel PNG image is a lot to store, and requires enough space to hold the entire standard configuration settings of the software. This makes the file size about 25MB, and that's only for the configuration settings - if you happen to encrypt a large text file, the total file size will be several hundred MB. Another problem is that you need to keep the passwords for Wuul Crypto Text, and even though you're not likely to change them every single day, you do need some way of backing them up, and having them stored in a location that isn't easily accessible. Finally, there's the issue of keeping a piece of software up to date - if you update Wuul Crypto Text, you have to update the configuration file and the software may require a restart to apply the changes. These issues are solved to a large extent in Wuul Crypto Text by applying an encryption technique called 4096-bit RSA, which doesn't encrypt the entire file (which would be about 3.3GB), but encrypts the file until the last bit, and fills the remainder with random garbage so that only you know the last bit - it takes a lot of space, but it gives you a lot of security. A disk backup is created. After decrypting a text file and copying it to the clipboard, you can then paste it into a document and edit it. When you change the text, the clipboard is copied back to the original file. If you want to revert your changes back to the original text, simply copy it to the clipboard again. You can encrypt any text file. After you've encrypted a file, you can use the up-arrow key to paste the encrypted plain text into a document and edit it. The plain text is then encrypted again, and the result copied to the clipboard. If you want to revert your changes back to the original text, you can copy the encrypted text to the clipboard again. You can easily keep a record of the password for later use. You can also encrypt multiple files by encrypting each file you have selected before you encrypt the first one. Insert the whole file into the compressed clipboard. Cut back to the original file and paste it into the editor. At this point, make sure you change the file name of the document to something other than the original filename. This way, the text within the encrypted text file is not changed, and the original file is not corrupted. The plain text is simply the result of reading the encrypted plain text data from the disk. The results of the encrypted text are those of AES-256 encryption. There are no known attacks that would be made that would uncover the contents of this text. However, this encryption process is done, and the results are not reversed. You cannot edit the plain text that you have encrypted. The plain text could be encrypted with your password, and you could not decrypt it. While the text is encrypted, it can be pasted into your clipboard.
