DOWNLOADSerial determinations of serum sodium in hospitalized patients: advantages and limitations. The routine determination of serum sodium in hospitalized patients has been a controversial practice. The authors report on their serial determinations of the mean serum sodium in 1,561 consecutively admitted patients to a general hospital over a 24-month period. They evaluate serum sodium measurements by

using the standard laboratory procedures of the United States Navy, Health Service Corps, and the British Ministry of Defence, and by using the standard methods of the American College of Emergency Physicians. They compare those results with the following characteristics of the patients: age, sex, diagnosis, baseline creatinine level, history of hypertension, serum creatinine level on admission, baseline

serum osmolality, and other pertinent laboratory data.

Although patients and patients' spouses were allowed to fill out questionnaires about the patients, the authors found no additional data that could not have been obtained from the data routinely collected for clinical purposes. They conclude that, in this population, sodium measurements are relatively inexpensive and can easily be obtained by the usual laboratory

tests, unless the patient is unstable or has an excessive sodium deficiency. In those latter situations, a basic serum sodium measurement immediately after admission should be considered mandatory to avoid injury or death from massive sodium imbalance.Q:
