Photo editors typically offer tools to make your images look better, make them more interesting, or add special effects to them. Photo editing is sometimes referred to as photoshopping. The term photoshop was coined by Scott Wilcox while working on the Kodak Motion Picture Imaging Color Negative System.[1] In the early years of the 20th Century, he worked to develop techniques to improve the grainy images taken by such cameras. The term "Photoshop" was originally coined by Wilcox in 1991 after he developed a series of software tools to enable users to improve the quality of such grainy images. He is reported to have coined the term to describe the series of tools. As you can see, most of the Photoshop Elements tools are saved on the left side of the Layer window. You can create new Layers with the Create a New Layer icon on the toolbar, and manipulate existing layers with the Edit Layers window. You can also save your current selection with New Selection, and create new selections with the Edit Selection tool.
- Fill:** Fill can be used to fill the selection with a predefined color or image. You can save your selection with New Selection.

N-acetyl-cysteine enhances the antibacterial action of daptomycin against *Staphylococcus aureus* biofilm. The aim of this study was to evaluate the effect of N-acetyl-L-cysteine (NAC) on antibiotic action against biofilm-embedded *Staphylococcus aureus*. The minimum biofilm eradication concentration (MBEC) of daptomycin against *S. aureus* biofilm was significantly lower in the presence of NAC. The addition of NAC did not affect the amount of biofilm or the cell viability of *S. aureus* cells. During treatment, the cell viability of *S. aureus* biofilms was lower in the presence of NAC compared to the control group. The results suggest that the combination of daptomycin with NAC can be an alternative treatment method for *S. aureus* infection. -fold capacity; therefore, the rate of erosions may be higher than observed in this study. However, it has been argued that the erosive potential of microorganisms is not solely dependent on the number of cells inoculated, but also dependent on growth conditions ([@CIT0010]), which would mean that a larger inoculum would lead to a higher number of persisting *S. mutans* cells and hence to a higher level of erosive potential. In conclusion, the results presented here show that *S. mutans* cells are able to induce greater amounts of enamel mineral loss by erosive challenge when compared with another oral pathogen, *S. sanguis*, in the absence of saliva. In contrast to the studies by [@CIT0022] and [@CIT0008], who reported that *S. mutans* caused little or no erosion of enamel, *S. mutans* was the most erosive oral pathogen in the present study. In addition, this is the first report to show that *S. mutans*-derived lipopeptides can induce erosion by means of the proteinaceous saliva of healthy volunteers. Finally, in addition to the original buffer used for rinsing before mineral loss measurement, other buffers were evaluated for the measurement of mineral loss. Rinsing with distilled water resulted in higher mineral loss values than in previous studies ([@CIT0008], [@CIT0022]). Most probably this was due to the higher pH of the buffers when compared
