Developing and maintaining reliable and efficient computer systems is an on-going task for system designers. For example, when the state of technology or processing demands changes, a system designer must update the design of computer systems to incorporate the new state of technology and the demands on the system. This is a continuous process that continues to this day. While the theory and practice of computer system design continue to change, the state of technology and the processing demands on the computer systems continue to change. In general, computer systems are not merely digital machines that perform operations specified by applications. Rather, some computer systems are composed of many integrated circuits, each of which may have their own design, specifications and methods of operation. As the state of technology continues to evolve, the demands on computer systems do as well. Consequently, inefficiencies in computer system design and implementation will continue to be discovered. These inefficiencies are usually addressed through research, development, implementation, testing, and verification. Research, development, and verification may be performed to develop new techniques and technologies, to test and analyze different designs, and to validate the operation of a system after implementation. Each of these activities may require performing simulations to test different design scenarios and to understand the behavior of the design under various conditions. One method of performing simulation in a computer system is the conventional "single instruction stream, multiple data stream" model. In this model, a stream of instructions is executed on a computer system. The single instruction stream is typically provided from a program being executed by the computer system. A program may be written in a high-level language, such as the C programming language. The high-level language may be compiled into a binary representation that includes instructions to be executed by the computer system. This single instruction stream executes on a single processing unit in the computer system. Different or multiple streams of instructions are executed on the multiple processing units in the system. This technique is typically efficient for highly parallel systems. Such systems with multiple processing units may include multiprocessor servers, workstations, or other processing devices, which are commercially available from companies such as the assignee of the present application, Hewlett-Packard Company. Single instruction stream, multiple data stream programming and execution in a computer system is conventionally performed using a compiler. The compiler processes the binary representation of the high-level language to produce instructions in the binary representation for the processing units of the system, such as the central processing unit (CPU) or other execution units within the processing units.

The 2.0.1.5 release of the perl-DebianTools package includes several translation updates. This version of perl-DebianTools corrects a problem with the french translation. The first part of the debian.pot file is now visible. The download page now has a link to the changelog. The most recent version of the DebianTools.pdf documentation has been published. In addition, important bugfixes have been introduced. Please read the changelog for more information.

(proj) double(ch, a, t, e, b, l, l, c, c1, f); s := m("x^2*X^2*(1+e^(t*X))^2"); printf("%f ", s); return 0; } A: the problem is that there are two references to this:pd(). The two references are not equal. That's what is causing the error you are seeing. namespace this { template void d() { std::cout void d() { std::cout (); template void d() { this:d(); } // the call to d is ambiguous for these 3 reasons: // 1. t:d, so t:d() // 2. d is a member of t, so :t:d(), inside of d(), // 3. there is an ::this:d(), inside of d(), // So the compiler stops and reports the ambiguity.
